WEEKEND SPECIAL · SECTOR REPORT

# The Nine-Year MEME Coin Ledger

*From DOGE's 654x to a -82% median — after Niulai and MARSCOIN, what this sector should actually be remembered for isn't the moonshot stories. It's the odds.*

Uncle Product · Crypto PM

Weekend Special · Sector Report

Data as of 2026-09-11

## Line up every MEME coin Binance has listed in nine years and run the numbers — what's the figure an ordinary participant actually walks away with?

Every MEME cycle produces its own **"654x"** or **"6000x"** story that gets reposted across every group chat. But across 495 Binance Alpha listings, the all-time return comes out to a mean of **-38.9%** and a median of **-82.4%** — the mean sounds survivable; the median tells a completely different story.

That gap is itself the evidence: a handful of moonshots drag the average up, while the typical, middle-of-the-pack project gets cut in half, then cut in half again. This weekend special lines up nine years of Binance MEME listings (2017–2026), 495 Alpha samples, 451 time-to-peak samples, and a fully-read MARSCOIN smart contract to answer one question: what do the real odds in this sector actually look like?

What an ordinary participant can act on isn't **"where's the next 654x"** — it's this: **time-to-peak is the cleanest quantitative signal available right now, multiple size and survival are two separate things, and the narrative is migrating from one chain to the next faster than ever.**

| 495 | -82.4% | -38.9% |
| --- | --- | --- |
| Binance Alpha listings sampled | All-time median return across 495 cases | Same-period mean return (skewed up by outliers) |
| **654.8x** | **39%** | **+66.6%** |
| DOGE's all-time-high multiple, the animal-coin ceiling | Share of cases that peaked within 1 hour of listing | Median return for cases still making new highs as of snapshot |

**Three-minute summary**

1. Binance MEME listing density is an inverse thermometer for cycle position: deep bear markets see almost zero new listings, bull-market peaks get a dense pileup. From May to September 2026, monthly new Alpha listings fell off a cliff, from 36-43/month at the peak down to 1-9/month — and Niulai and MARSCOIN were both born right in this quiet window.
2. Of the landmark MEME coins with a full nine-year data trail, only three — DOGE, SHIB, PEPE — qualify as "long-term brands" (about 15%); "one-shot fireworks" make up 75-80%.
3. The animal-coin multiple ceiling is decaying generation over generation: **DOGE 654.8x** >> **PEPE 28.75x** > **SHIB 17.46x** — whoever captures the category dividend first always captures the most.
4. Multiple size and "can it survive long-term" are two different things: PEPE (28.75x) and PNUT (25x) were nearly identical in mania at launch — PEPE went on to make a fresh high, PNUT still sits -91% below its peak.
5. Across 495 samples: the gap between a **-38.9%** mean and a **-82.4%** median is the statistical proof of a **"most go to zero, a few get rich"** long-tail structure — only **20%** of MEME-sector projects are still **positive all-time**.
6. Time-to-peak is the largest-sample (451), cleanest signal available: coins that peaked within an hour of listing have a median outcome of **-87.3%**, while coins still making new highs as of the snapshot have a median outcome of **+66.6%** — a clean, monotonically increasing gradient.
7. TRUMP's and BOME's real rallies happened almost entirely on-chain before their Binance listings — Binance retail was **purely left holding the bag**; a spot listing is a better reduce-risk signal than a buy signal.

8. MEME mania keeps migrating between chains: Solana was the main battlefield in 2024, BNB Chain has repeatedly ignited things via official personal moves since 2025, and Robinhood Chain has surged since July 2026 with its own "meme + tokenized equity" hybrid category — MARSCOIN is a parallel case of that same narrative on a different chain.
9. MARSCOIN's tax-and-dividend mechanism has now been verified by reading the source code plus live on-chain state: the 3% buy/sell tax is locked into the token contract, but how that tax gets split and how high the dividend threshold sits is left to the platform's discretion; withdrawing from an exchange to a personal wallet is confirmed to legally dodge the tax without hurting dividend eligibility.

# Listing Density: An Inverse Thermometer for Cycle Position

Lay out nine years of Binance MEME listings along a timeline and a clean pattern emerges: **deep bear markets see almost zero new MEME listings, the early bear-recovery phase gets one or two "restart flares," and bull-market peaks get a dense pileup**. This isn't a vibe — it's countable, period by period.

| CYCLE PHASE | TIME | BTC PRICE RANGE | LISTING FREQUENCY | REPRESENTATIVE CASES |
|---|---|---|---|---|

| | | | | |
|---|---|---|---|---|
| Founding + ICO mania → bear | 2017-2018 | <$1K → $19.7K → deep bear | Zero listings | — |
| Early bear recovery | 2019 | $11-12K | Very low, "restart flare" | DOGE spot (7-05) |
| Dog Coin Summer → peak | 2020-2021 | $9.2K → $64.8K | Rising → dense pileup | DOGE perp, SHIB (2021-05) |
| Deep bear market | All 2022 → 2023-04 | $47K → $15.8K bottom | Zero listings (confirmed gap) | — |
| Early bear recovery | 2023-05 | $29K | Very low, "restart flare" | PEPE + FLOKI (5-05) |
| Mid-bull market | H2 2023 – H1 2024 | $35K → $73K | Clearly rising | BONK, WIF, BOME, MEW |
| Bull-peak pileup | Q4 2024 – Q1 2025 | $80K → $108K | Highest frequency | PNUT, PENGU, FARTCOIN, TRUMP |
| BNB Chain shill-driven phase | All of 2025 | Range-bound | Intermittent pulses, tied to official moves | Mubarak series, "Binance Life" (6000x) |
| Current phase | H2 2025 – 2026 | Data gap | Alpha→perp→spot funnel; Robinhood Chain surges | MARSCOIN, Niulai, CASHCAT, PONS |

The pattern now has precise numbers behind it, not just a qualitative read. Monthly counts of new Binance Alpha listings:

| PERIOD | AVG. ALPHA LISTINGS/MONTH | NOTE |
|---|---|---|
| 2025-06 to 2025-10 (peak) | 36-43/mo | The five densest months of the whole cycle |
| 2025-11 to 2026-04 | 16-32/mo | Steadily cooling |

| | | |
|---|---|---|
| 2026-05 to 2026-09 (recent) | 1-9/mo | Cliff-edge drop — just 3 in July, 1 in September |

> **MARSCOIN and Niulai landed right in this dead zone.** This isn't "it feels quieter lately" — monthly new listings genuinely fell off a cliff, from 20+ down to single digits. Both are among the rare exceptions in this quiet window, worth keeping in mind when placing them on the cycle.

02

## 13 Landmark Cases Across Nine Years

Every multiple in the table below comes from Binance/TradingView weekly charts, manually verified "listing low → all-time high" real prices — not estimates:

| COIN | CHAIN | LISTING STAGE/DATE | CYCLE POSITION | MULTIPLE | OFF ATH | TYPE |
|---|---|---|---|---|---|---|
| DOGE | Litecoin fork (multi-chain bridged) | Spot 2019-07-05 | Early bear recovery | 654.8x | -88% | Long-term brand |
| SHIB | Ethereum | Spot 2021-05-10 | First peak | 17.46x | -94% | Long-term brand |
| PEPE | Ethereum | Spot 2023-05-05 | Early bear recovery | 28.75x | -87% | Long-term brand |
| FLOKI | Ethereum/BSC dual | Spot 2023-05-05 | Early bear recovery | 22.9x | -92% | One-shot firework |
| BONK | Solana | Spot 2023-12-15 | Mid-bull | 6.68x | -95% | One-shot firework |
| BOME | Solana | On-chain 2024-03-13 | Local bull peak | 186x* | -96% | One-shot |

| | | | | | | |
|---|---|---|---|---|---|---|
| | | → Spot 2024-03-16 | | | | firework |
| PNUT | Solana | Spot 2024-11-11 | Post-election acceleration | 25x | -91% | One-shot firework |
| TRUMP | Solana | On-chain 2025-01-17 → Spot 2025-01-19 | Peak zone | 64.4x* | -97% | One-shot firework |
| POPCAT | Solana | Spot ~2024-09-07 | Bull peak | 4.49x | -97.5% | One-shot firework |
| PENGU | Solana | Spot 2024-12-17 | Near peak | 20.74x | -88% | One-shot firework |
| FARTCOIN | Solana | Perp 2024-12-20 | Near peak | 4.17x | -93% | One-shot firework |
| MARSCOIN | BNB Chain | Alpha 7-30 → Perp 9-01 → Spot 9-04 | Current phase | Cycle incomplete | -47% (interim) | TBD |
| Niulai (NIULAI) | BNB Chain | Alpha 8-18 → Perp late Aug → Spot 9-09 | Current phase | Cycle incomplete | Too recent | TBD |

* BOME's and TRUMP's real multiples happened in the on-chain phase before their Binance spot listing — see note below.

**PENGU, BOME, and TRUMP all show "low = high, same day" — but that's three different truths.** PENGU's 20.74x genuinely happened within Binance trading hours — the whole low-to-high run played out on listing day, so retail theoretically had a shot, just compressed into under 24 hours. BOME (real 186x) and TRUMP (real 64.4x) are different: nearly all of their real upside happened on-chain *before* the Binance spot listing, so by the time Binance listed them, price was already near the top. **Retail on Binance never captured**

> **a single leg of the real rally — pure bag-holding** — hard evidence that this is a **"brand play"** using a Binance listing as the final distribution event, no longer just a hunch.

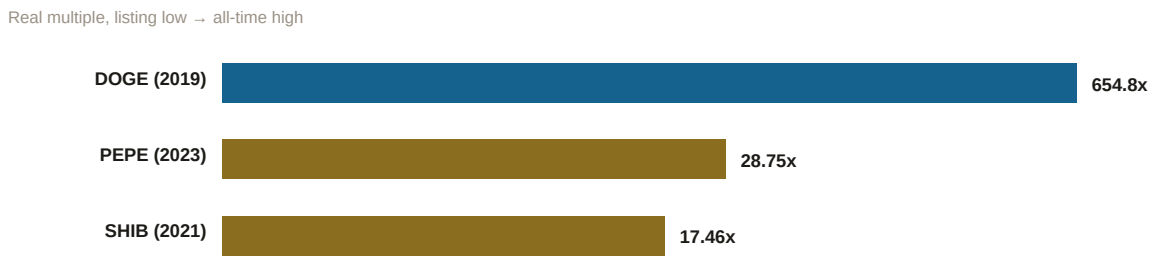

03

# Long-Term Brands vs. One-Shot Fireworks

Of roughly 20 well-documented, name-brand cases, **only three — DOGE, SHIB, PEPE — qualify as long-term brands, about 15%**; the remaining 75-80% are one-shot fireworks that never returned to a meaningful high again. Of the three, only PEPE went on to set a fresh all-time high the next cycle; DOGE dropped 92% off its 2021 peak, then rallied back to 66% of ATH by late 2024; SHIB rallied back to 52.6% of ATH but never got close to reclaiming it. Everything else remains 90-98% below its peak to this day.

What the "long-term brand" trio actually share isn't "being an animal" — it's everything beyond the animal: archetypal cultural status ("the original dog coin," "the original frog coin"), community continuity across cycles, ongoing narrative extension (SHIB's Shibarium, DOGE's long-running celebrity endorsements), and being early enough to reach broad distribution.

Fig. 1 — The animal-coin multiple ceiling is decaying generation over generation: whoever captures the category dividend first always captures the most (log-scale axis, real multiples labeled)

DOGE → PEPE drops a full order of magnitude; with only two "animal-original" points so far, the direction is sound but the sample is thin — even a coin that repeats this path should land well below PEPE, and further still below DOGE.

## Multiple size and "can it survive" are two independent axes

Put PEPE (28.75x, long-term brand) next to PNUT (25x, one-shot firework) and the two were nearly identical in mania at launch — but PEPE went on to make a fresh high the next cycle, while PNUT still sits -91% below its peak. POPCAT (4.49x) has a lower multiple than BONK (6.68x) and isn't any safer for it. **Surviving a crash has no necessary relationship to how hard it pumped at launch** — survival comes down to cultural-archetype status and

community continuity; the multiple only tells you how manic things got at the time. Don't use the latter to predict the former.

### "Has backing = it's a rug" needs unpacking

A common read: any MEME that lists at a BTC cycle peak, posts a huge multiple, and has visible "backing" is basically a designed harvest play. Directionally that's mostly right, but it needs unpacking — TRUMP is the case that best fits the description (official platform support + roughly 80% of supply concentrated in team/affiliated wallets), yet PNUT and POPCAT had zero official backing and ended up just as badly. **The real deciding factor is more likely "did the listing land inside BTC's most euphoric window," not "was there backing" per se.** A more actionable signal is the time span from listing to all-time high: DOGE took about 16 months, PEPE about 8 months to peak, with a genuine price-discovery process in between; "peak-on-arrival" coins like TRUMP and BOME topped out in hours to a day. The faster the time-to-peak, the more it looks like a designed harvest — a signal validated on 451 samples in the next section.

04

## 495 Samples: The Mean Lies, the Median Tells the Truth

Everything so far has been hand-picked, well-known cases, which invites survivorship bias. This section switches to a complete dataset covering 495 Binance Alpha listings across 8 sectors — the first time we can validate the earlier read on a large sample instead of "20 hand-picked names."

| HOLDING PERIOD | FULL-SAMPLE MEAN | FULL-SAMPLE MEDIAN |
|---|---|---|
| +1 hour | +6.5% | 0% |
| +24 hours | +11.4% | -4.6% |
| +7 days | +8.5% | -14.5% |
| +30 days | -0.1% | -30.8% |
| All-time | -38.9% | -82.4% |

> **The all-time mean is down only 39%; the median is down 82% — that gap is the evidence.** A handful of moonshots (MARSCOIN itself is +1471%) drag the average up, but the typical project in the middle of the pack gets cut in half, then cut in half again. This isn't cherry-picking bias — it's just what this sector's return distribution actually looks like: extreme right skew, long tail.

The MEME sub-sector specifically (85 samples): **42.4% delisted**; all-time median -78.7%, while the mean is actually +37.5% (again dragged up by extreme moonshots); **only 20% of MEME coins are still positive all-time**, 74.1% are negative, and 40% are down more than 90%. Broken down by sector, all-time median:

| SECTOR | SAMPLE SIZE | DELISTING RATE | ALL-TIME MEDIAN |
|---|---|---|---|
| RWA · Tokenized equity* | 23 | 17.4% | 0% |
| DePIN | 21 | 23.8% | -56.7% |
| MEME | 85 | 42.4% | -78.7% |
| DeFi | 71 | 46.5% | -78.8% |
| Social/Consumer/Content | 24 | 33.3% | -81.2% |
| L1/L2/Infrastructure | 156 | 36.5% | -82.0% |
| AI · Agents | 74 | 52.7% | -89.5% |
| GameFi · Metaverse | 39 | 64.1% | -94.0% |

* RWA · Tokenized equity is mostly a low-volatility mirror of real stock prices with none of MEME's speculative swings — the flat median just reflects that these barely move either way, so it isn't a fair comparison to MEME. MARSCOIN is explicitly classified as MEME in this dataset, not RWA.

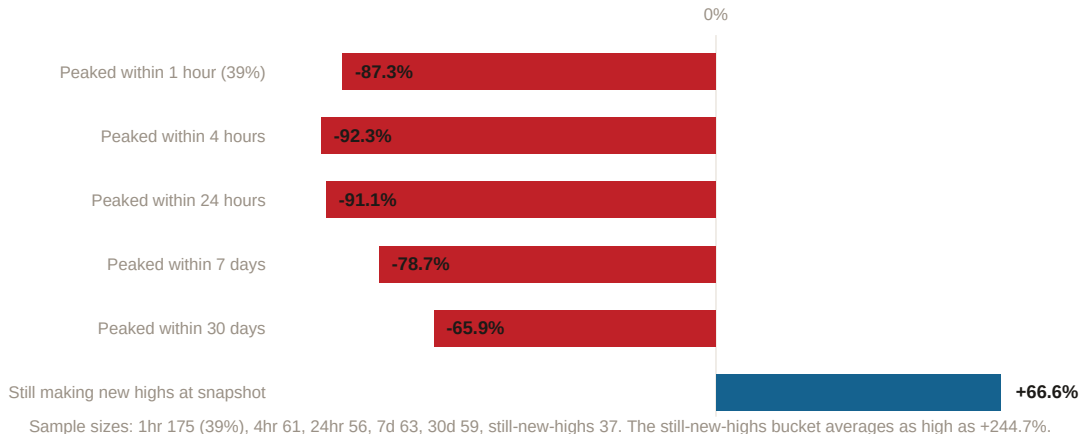

05

## Time-to-Peak: A Monotonic Signal Validated Across 451 Samples

"The faster it peaks, the worse it ends" now has statistical backing across 451 samples — no longer a handful of anecdotes. Grouped by which checkpoint the peak fell in, here's the all-

time median:

Fig. 2 — The later the peak, the better the outcome: an unusually clean monotonic gradient (451 samples, all-time median return)

Sample sizes: 1hr 175 (39%), 4hr 61, 24hr 56, 7d 63, 30d 59, still-new-highs 37. The still-new-highs bucket averages as high as +244.7%.

> **This pattern can now be treated as a core screening signal.** Peaking within an hour of listing is the single most common outcome across all 495 Alpha listings (39%) — "peak on arrival" isn't a rare edge case, it's the single most likely outcome in this sector. A new coin that goes longer without making a new high deserves more attention, not less; conversely, one that spikes and fails within a very short window should be filed straight into the high-risk "brand play" bucket, whether or not there's confirmed backing behind it.

06

## The Three-Stage Listing: Amplification and the Bag-Holder Trap

Alpha → perpetuals → spot is Binance's standard three-stage MEME listing sequence, and each stage in theory adds another leg of price amplification. But cleanly isolating each stage's individual contribution requires two conditions at once: no information leaking early, and BTC staying calm through that exact window — the two rarely line up together. The shorter the window and the calmer the broader market, the cleaner the separation; otherwise it's hard to disentangle.

The only case so far with a fully verifiable, stage-by-stage timeline is MARSCOIN (BNB Chain): Alpha (7-30) → perps (9-01, 20x leverage) → spot (9-04). It was still range-bound at

$0.04-0.06 in late August, spiked to an all-time high of $0.16-0.26 on spot-listing day, gained roughly +288% in a week, and open interest jumped from $2M to $34.64M.

> **Spot listing works better as a reduce-risk/short signal than a buy signal.** PEPE peaked and rolled over just 40 minutes after its spot listing; MARSCOIN's spot-listing day was its all-time high, and it's been falling since. This lines up with Section 02's finding — TRUMP's and BOME's real rallies happened almost entirely on-chain before the Binance listing, leaving Binance retail purely holding the bag.

07

## On-Chain Migration: The Narrative Keeps Moving House

Lay new-chain and new-platform narratives out along a timeline and MEME mania is migrating between chains on a clear rhythm — and the cycle itself is compressing from "a season" to "a week" (a 2021 wave lasted 3 months; December 2024's lasted just 6 days):

| TIME | CHAIN | NARRATIVE | REPRESENTATIVE DATA | HOW IT FADED |
|---|---|---|---|---|
| 2021 | BSC | BSC + SafeMoon | Peak market cap over $8B | Team lawsuits, effectively zeroed out |
| H1 2024 | Base | Base chain | BRETT market cap over $1B | Sharp pullback in 2025 |
| 2024-2025 | Solana | Solana + Pump.fun | 71.1% of Solana token mints at peak | Daily actives halved, FDV to $2.4B |
| 2025-03 | BNB Chain | Mubarak series (CZ personally bought in) | Single-coin peak cap over $270M | Fast peak, propped up by official moves |
| 2025-10 | BNB Chain | "Binance Life" — sparked by one reply from He Yi | $0 → $500M cap in 96 hours, 6000x | Long fade after a 96-hour spike |
| 2026-present | Robinhood Chain | "Meme + tokenized equity" hybrid | PONS up 100x+; on-chain MEME cap at times tens of times | Ongoing, already cooling |

tokenized-equity assets

As of mid-2026, the altseason index (ASI) has held around 30-37 without ever touching the "confirmed altseason" threshold of 75 — this looks more like a short-lived, sector-specific "mini rotation" than a classic full-blown altseason.

## Robinhood Chain: a category vacancy nobody else has, and an expiry date on the calendar

Robinhood Chain went live on mainnet July 1, 2026, originally meant for stock/ETF tokenization — but on-chain data shows **92.9% of wallets have only ever touched MEME tokens**, with just 3.7% having touched tokenized-equity assets at all. It's the most extreme case observed so far of MEME "hijacking" a chain's intended purpose. That's also created a category vacancy no other chain has: a MEME hybrid tied to real equity/dividend mechanics. MARSCOIN was issued on BNB Chain rather than Robinhood Chain itself, but its narrative logic is structurally identical to this new category — a parallel case of the same story playing out on a different chain.

> **A structural risk written on the calendar: September 29, 2026, 23:59 EST.** Robinhood subsidizes gas for certain in-wallet transactions on a 90-day window from launch — that's the expiry date. Total gas spend under the subsidy jumped 82x in 11 days, suggesting a meaningful share of current activity is artificially propped up by "free." After September 29, DEX volume, protocol fee revenue, and how many MEME traders convert into genuine users are the three metrics that will show whether this chain can sustain real activity independent of the subsidy.

> **A market rumor that needs its evidence boundary flagged: "Binance deliberately favors BSC MEME coins."** The confirmable pattern is real: Binance's core leadership has repeatedly personally bought into or publicly endorsed BSC MEME coins, producing a clear official-endorsement effect (the Mubarak series, "Binance Life"). But "Binance runs a systematic strategy to suppress other chains in favor of BSC" is a claim about intent that no official or credible source confirms — it should be flagged as market rumor / KOL interpretation, not treated as fact for trading decisions. One data point that cuts against the "deliberate suppression" narrative: Binance's Web3 wallet already added Robinhood Chain token-trading support in July 2026.

08

# Case Study: Niulai vs. MARSCOIN

DOGE is a dog, PEPE is a frog — the long-term brands are all "original animal" coins. Niulai is itself built around an ox/cow image — does that give it a better shot at repeating the pattern than MARSCOIN? Both launched on BNB Chain, making this an apples-to-apples comparison within the same chain, representing two different, non-mutually-exclusive paths to long-term potential.

| COIN | CHAIN | ALPHA LISTING DATE | LISTING PRICE | RETURN TO DATE | DELISTED? |
|---|---|---|---|---|---|
| MARSCOIN | BNB Chain | 2026-07-30 | $0.00401 | +1471.2% | No |
| Niulai (NIULAI) | BNB Chain | 2026-08-18 | $0.03107 | +152.2% | No |

As of this data snapshot, MARSCOIN's gain from its Alpha listing price is roughly 6x Niulai's — that's only "who's up more so far," not "who has more long-term brand potential."

One key detail: at each coin's own listing moment, BTC wasn't at a cycle top — over each coin's life span BTC rose from roughly $64K to about $79.5K (+24.1%), never breaking the prior cycle's roughly $100-109K all-time high. That puts both closer to a "post-bear recovery / early-to-mid bull" reference frame — more like PEPE (which listed during the 2023 bear recovery) than TRUMP/PNUT/PENGU, all of which listed at cycle peaks.

**The case for Niulai taking the "original animal" route**

"Ox/cow" has no widely recognized Western original-animal representative yet — it's an open category slot. In Chinese financial slang, "牛" (ox/cow) is already synonymous with "bull market," a positive association baked into the culture independent of price — something neither DOGE nor PEPE has at the language level. But DOGE's and

**MARSCOIN's potential: a different track entirely**

It's tied to a real-asset dividend mechanism (SPCXB/tokenized SpaceX equity) — a "meme + real cash flow" hybrid model, different from DOGE/PEPE's pure culture-symbol-driven approach. Robinhood Chain has independently produced the exact same "meme + equity" narrative with zero connection to MARSCOIN, suggesting

PEPE's real moat was never "being an animal" — it's the years of cultural symbolism built up beyond the animal itself. Niulai has no comparable cultural accumulation independent of price yet, and only about a month of history — a sample size of "zero complete cycles."

this isn't one project's isolated design — it's a new category hypothesis multiple chains are testing at the same time, right now.

These represent two structurally different long-term potential paths; the sample window is far too short to make a confident call either way. What's worth watching is how each coin holds up in the next deep pullback or narrative cooldown — that's the first real stress test of whether either has genuine long-term brand potential.

09

# MARSCOIN's Dividend Mechanics: Three Things the Contract Confirms

If spot is already listed, why is anyone still buying on-chain? Does the tax have an expiry? Can you withdraw and dodge the tax while still collecting dividends? Three questions that used to be pure speculation — this round nails all three down with real contract data.

▸ Expand: MARSCOIN-related contract addresses

## One: the 3% buy/sell tax is locked at the token layer, but the platform can still change how it's split

On-chain real-time reads confirm a 3% tax on both buys and sells, hard-coded into the token contract's storage with no function able to change either number, and the token contract's owner has renounced ownership to the zero address — the only "expiry mechanism" works out to the year 2126, effectively permanent. But **how the collected tax gets divided up is not locked** — the owner of the distribution-logic contract is Flap's central platform contract, which has not renounced ownership and can change the split ratio and dividend threshold (currently 10,000 tokens) at any time. The 3% rate itself is hard to change, but how that 3%

gets split and how high the dividend threshold is left as a backdoor for the platform — not a fully immutable promise.

### Two: the 3% tax isn't 100% to users — it's 90%, correcting an earlier rumor

Reading the distribution contract in real time: of every 3% total tax on a trade, **0.3% goes to the Flap protocol layer, and 2.7% (90% of the total tax) actually flows into the SPCXB dividend pool**. An earlier online claim said "100% goes to buy back SPCXB" — on-chain data doesn't support that.

### Three: withdrawing to a personal wallet is confirmed to dodge the tax without hurting dividend eligibility

The tax logic only triggers when a transfer involves the mainPool — checking the two common external liquidity pools directly in the contract, both come back untaxed, meaning trades through those pools aren't taxed, and an ordinary exchange withdrawal to a personal wallet definitely doesn't touch mainPool either, so it isn't taxed. Dividend eligibility only looks at your real-time balance after the transfer — it has nothing to do with where the coins came from. **Buying on an exchange and withdrawing to your own wallet is confirmed to dodge the 3% buy tax without losing dividend eligibility — a fully compliant path proven by the on-chain mechanics**, which also directly answers "who's still buying on-chain after the spot listing": self-custody on-chain gets you faster, more certain dividends, and skips the buy/sell tax.

10

## Chain Classification and a Heat Snapshot

Which chains MEME mania migrates between has so far been scattered across individual case studies in earlier sections, without a systematic framework. Here's a unified classification:

| CATEGORY | CHARACTERISTICS | TYPICAL ISSUANCE/TRADING VENUE |
|---|---|---|
| Ethereum mainnet / legacy | The original chain for legacy-tier MEME coins; high cost to launch, few new coins | Direct deployment + Uniswap |

| L1 | | |
|---|---|---|
| Solana ecosystem | Lowest launch barrier, dominant battleground during 2024-2025 peak, activity now well off its highs | pump.fun |
| BNB Chain ecosystem | Official personal-action-driven pulse bursts, fades just as fast | Four.meme, Flap (MARSCOIN's launch platform) |
| Base ecosystem | Cold-started off Coinbase's distribution advantage; that traffic hasn't converted into the chain's own financial activity | Various DEXs |
| Robinhood Chain ecosystem | Meant for equity tokenization, MEME unexpectedly took over; a unique "meme + equity" hybrid category vacancy | Pons, hood.fun, Pools.trade |

A cross-chain heat snapshot table has just been established, meant to keep tracking "which chain is hottest right now" — the same table will accumulate new entries after each future analysis:

| RECORD DATE | HOTTEST CHAIN RIGHT NOW | BASIS |
|---|---|---|
| 2026-09-11 | Robinhood Chain (short-term); BNB Chain (pulses ahead on official personal moves) | Robinhood Chain's on-chain MEME market cap has at times run tens of times its tokenized-equity assets; BNB Chain has a track record of pulse-driven bursts. Solana and Base are comparatively quiet, with no new breakout narrative observed. |

> Right now there's only 1 recorded entry — nowhere near statistically meaningful. "Which chain is hottest" should be treated as a point-in-time observation snapshot until more data accumulates, not a pattern to rely on yet.

11

## What We Couldn't Verify

> **This piece's citation discipline: every number is either sourced or explicitly flagged "unverified" — no guessing.** Here's what remains uncertain:

- Sections 03 and 08's roughly 20 hand-picked, well-known cases have limited statistical weight; the 495/451-sample datasets in Sections 04/05 are the real large-sample validation. Even so, the 495-case Alpha dataset covers 2024-12-18 through 2026-09-02 and hasn't been independently verified for data source or methodology (e.g., what baseline "all-time excess return" is measured against isn't specified).
- Different data sources disagree on the same coin's all-time-high price/market cap; this piece uses the manually-verified chart data as the multiple of record. BOME's and TRUMP's on-chain launch-date records appear to contain year typos in the original source; this piece applied what looks like the more reasonable date and calculated multiples on that basis — worth re-verifying the original dates later.
- The DOGE → PEPE generational-decay pattern in multiples rests on just two data points; the direction is reasonable but the sample is far too small to be a rigorous rule. The time-to-peak pattern, by contrast, is validated on 451 samples and is meaningfully more reliable.
- The Section 08 "resilient MEME candidates" shortlist and the observation about "a disproportionate share having Chinese-language names" are both exploratory findings on a small sample — not a bettable pattern — and more than half of the coins in that set still have their chain affiliation marked "unconfirmed," which is a deliberate gap, not an oversight.
- The Section 08 Niulai vs. MARSCOIN long-term-brand-potential discussion remains speculative and is not investment advice; both coins have only just over a month of trading history. That said, their BTC-cycle-position data has been verified via on-chain timestamps plus candle data and is factual.
- MARSCOIN's dividend mechanism has been verified via contract source-code review and live on-chain state queries; the one remaining open question is whether an ordinary Binance spot holder automatically qualifies for dividends, or whether it's restricted to specific verified identities — public materials don't make this clear.
- Section 10's chain classification and heat snapshot is a newly established framework with only 1 recorded entry so far, nowhere near statistically meaningful; speculation about "whether Binance favors a particular chain" is explicitly not treated as fact in this piece — it's recorded only as market rumor with its evidence boundary flagged.

Put all these numbers together and the real lesson of this sector isn't "where's the next 654x" — it's this: **multiple size and survival are two**

**separate things, timing explains who gets rugged better than backing does, time-to-peak is the cleanest quantitative signal available, and the narrative keeps moving house from one chain to the next faster than ever** — the people chasing the story are always chasing the chain that already finished running.

MARSCOIN and Niulai are both still firmly **"TBD"** — barely two months of sample history — so any call on whether either becomes the next DOGE or the next PEPE is premature. What's actually worth tracking is how each holds up in the next deep pullback, and Robinhood Chain's date on the calendar — **September 29** — both of which will answer **"who survives"** far better than any multiple does right now.

> Two things to watch next: how MARSCOIN and Niulai hold up in the next deep pullback; and Robinhood Chain's **2026-09-29** gas-subsidy expiry, written on the calendar.

**Data & methodology:** Binance historical listing announcements and candle data, TradingView weekly charts (manually verified low/high prices), Binance Alpha's official performance dataset (495 projects, 2024-12-18 to 2026-09-02 snapshot), MARSCOIN/Niulai contract code and live on-chain state reads, Robinhood Chain and Flap public data. Every figure in this piece is sourced in the body text or flagged in Section 11; anything untraceable is marked "unverified" or "market rumor," never presented as fact.

This piece is mechanism analysis and data reporting only — not investment advice. MEME coins are extremely volatile and carry high liquidity risk; past performance doesn't predict future results. Make your own judgment and bear your own trading risk.
